

a

$$\Delta\phi'_{f,g}(t) = \Delta\phi_{f,g}(t) - t(\hat{\beta}_{f,a} - \hat{\beta}_{g,a})$$

Independent slopes add an unwrapped relative correction proportional to time (wrapped modulo 2π).

Shared alternative: $\hat{\beta}_a = \text{median}_f \hat{\beta}_{f,a}$
All subcarriers use the same slope, so $\hat{\beta}_{f,a} - \hat{\beta}_{g,a} = 0$.

A shared slope preserves cross-subcarrier phase differences.
